

HEATER FOR PHYSIOLOGICAL FLUIDS

FIELD OF THE INVENTION

This invention relates to the art of devices used with physiological fluids. In particular, the invention is an apparatus for heating a physiological fluid before introduction into a patient.

BACKGROUND ART

In many medical procedures, it is necessary that fluids to be administered to a patient be heated. For example, whole blood and packed cells are stored in refrigerators at a temperature of approximately 4° C. These fluids often are required to be administered to a patient within a short period of time, which necessitates warming them to a temperature approximately equal to that of the patient, i.e. 37° C.

Great care must be exercised when heating fluids such as whole blood or packed cells to avoid damaging the cells. For example, it is generally accepted that whole blood and packed cells should not be exposed to a temperature above 44° C. This places a severe restriction on the techniques used to heat quickly fluids which have been stored in a refrigerator and which must be administered to a patient within a short period of time.

U.S. Pat. Nos. 3,614,385 (Horstmann), 3,629,552 (Edging), 4,476,867 (Parks), and 4,532,414 (Shah et al.) teach systems for heating blood prior to being administered to a patient. The Horstmann, Edging, and Parks devices use various heat exchangers whereby blood flows through a tube which communicates with a warming fluid in a heat exchanger. It is quite difficult to maintain sterility of the heating apparatus in these systems after the first use because of the complexity of the heat exchangers. The Shah et al. device is simply a heated plate having a groove therein for receiving a tube leading from the bag containing the fluid to be administered.

U.S. Pat. No. 2,910,981 (Wilson et al.) shows a device for conducting blood transfusions. A heat exchanger is in fluid communication with a heating element, and the blood to be administered passes through the heat exchanger before being administered to the patient. The heat exchanger comprises a central tube surrounded by an outer tube, and the heating fluid passes through the space between the inner and outer tubes. The heat exchanger is threadedly connected to valves at opposite ends. No structure is described for supporting the various elements described in the patent.

SUMMARY OF THE INVENTION

The invention is a self-contained, free standing system which permits controlled, but rapid heating of cellular fluids as they are being administered to a patient. The heating of the cellular fluids is controlled to prevent damage to the fluids from various causes including overheating.

The system comprises two major parts. A first part includes a heating element, a support pole, and a wheeled base. A second part comprises a heat exchanger and, optionally, a filter. The heat exchanger and filter are disposable and are removably attached to the support pole. The heat exchanger is disposable to facilitate each patient's use of a new, sterile heat exchanger.

The heat exchanger is easily installed on the pole, which includes a fixed mounting block and a movable

BEST AVAILABLE COPY

mounting block. Opposite ends of the heat exchanger comprise nipples which are received in O-ring retaining recesses in the mounting blocks. Thus, installation and removal of the disposable heat exchanger are quite easy.

The system may also include a filter which would be attached to an outlet of the heat exchanger. Sensors on the pole detect when the heat exchanger or the filter is in a correct place to control operation of the heating system.

The heating system comprises a tank and a heating element in the outlet line of the tank. A pump circulates a heating fluid from the tank and heating element through the disposable heat exchanger.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an exploded view of the apparatus in accordance with the invention.

FIG. 2 is a longitudinal cross-section of the support pole.

FIG. 3 is a longitudinal cross-section of the heat exchanger.

FIG. 4 is an enlarged cross-section of an upper end of the support pole.

FIG. 5 is an exploded perspective of a movable mounting block and the upper end of the support pole.

FIG. 6 is a side view of the upper end of the support pole shown in FIG. 4.

FIG. 7 is a perspective view of the heating element with the cover removed and the storage tank shown in phantom lines.

FIG. 8 is a schematic view showing the preferred fluid circuit.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 is an exploded view of a preferred embodiment of the invention. A base 2, which preferably has wheels for ease of mobility, supports a pole 4 and a heating unit 6. Pole 4 removably receives a disposable unit 8 which includes a heat exchanger 10 and a filter 12. Tube 14 is in fluid communication with one end of heat exchanger 10 and connects it to a pair of bags 16. The bag spikes are known in the art and are used to puncture and allow the dispensing of a body fluid from a storage bag. Tube 18 connects a lower end of heat exchanger 10 to an upper end of filter 12 and tube 20 connects a lower end of filter 12 to cannula 22 to allow fluids to be introduced into a patient.

As will be more fully described below, the entire unit 8 is manufactured of an inexpensive material and is disposable to ensure sterility.

FIG. 2 is a longitudinal cross-section of pole 4 with heat exchanger 10 partially mounted thereon. Pole 4 includes a housing 24 which is attached to base 2 (FIG. 1) to extend substantially vertically. Housing 24 is preferably a hollow square tube, and hoses 26 and 28 extend along a hollow portion of housing 24. Preferably, hoses 26 and 28 exit housing 24 via opening 30. In addition, electric conductor 32 extends along the hollow portion of housing 24 and exits by way of a second opening 34.

Heat exchanger 10 is removably received by first detachable fluid connector 36 and second detachable fluid connector 38. The structure of fluid connectors 36 and 38 will be more fully described with respect to FIGS. 4 and 8. Detachable fluid connector 36 is mounted for vertical movement with respect to housing

BEST AVAILABLE COPY

24 to allow heat exchanger 10 to be easily attached to pole 4 and detached. Accordion element 40 is placed in hose 28 to permit fluid connector 36 to move vertically. Sensor 42 detects when fluid connector 36 is in its lowermost position (as shown in FIG. 4), sensor 44 detects when heat exchanger 10 is in an operable position, and sensor 46 detects when filter 12 is in operable position.

Filter 12 is supported on pole 4 by U-shaped bracket 48. The distance between the legs of the bracket is slightly less than the diameter of the filter so that it "snaps" into place. Similarly, a U-shaped bracket 49 is located between connectors 36 and 38. Bracket 49 holds heat exchanger 10 aligned with connector 36 during insertion of the heat exchanger.

FIG. 3 is a longitudinal cross-section of heat exchanger 10. An inner tube 50 has ends 52 and 54 which are adapted to be received in respective fluid connectors 36 and 38. A central portion 56 of tube 50 is helically shaped to provide a helical groove on the exterior of tube 50. Tube 50 is preferably made of aluminum, and the helical surface is produced by twisting the tube.

An outer tube 58 fits over the inner tube 50 in a central portion thereof. The space between the helical central portion 56 and the outer tube 58 forms a helical path extending between opposite ends of outer tube 58.

An inlet connector 60 is secured to one end of outer tube 58 and includes connection 62 which receives tube 14 (see FIG. 2). End 52 of inner tube 50 extends beyond the upper edge of inlet connector 60 to provide a nipple for engagement with fluid connectors 36 as will be more fully described with respect to FIG. 4.

Outlet connector 64 is secured to a second end of outer tube 58, provides connection 66 for attachment to tube 18, and allows end 54 to project to form a nipple for being received in fluid connector 38.

FIG. 4 is an enlarged cross section of an upper end of pole 4. Housing 24 has a slot 68 in one side thereof for receiving a projection 70 from fluid connector 36. Projection 70 has outwardly extending ears 72 (see FIG. 5) to secure the fluid connector to the pole and yet to allow it to move in the direction indicated by the arrow in FIG. 4.

Elbow 74 is threadedly connected to projection 70 to connect hose 28 with inner passage 76. Recess 78 connects with passage 76 and receives nipple end 52 of heat exchanger 10. O-ring seal 80 is received in an enlarged portion of recess 78 to provide a fluid-tight seal. It will be appreciated that fluid passing through hose 28 is thus connected to inner tube 50 of heat exchanger 10.

FIG. 5 is an exploded view of the fluid connector 36 and the upper portion of housing 24.

Fluid connector 38 is similar to fluid connector 36, except that connector 38 is secured to housing 24.

It will be appreciated that heat exchanger 10 may be easily attached to pole 4 by inserting end 54 into fluid connector 38 and by lowering fluid connector 36 onto end 52. When this is accomplished, heat exchanger 10 will be supported mainly by fluid connectors 36 and 38.

FIG. 6 is a side view of the top portion of pole 4 with a bracket 82 shown in cross-section. Bracket 82 has a hole therethrough for supporting a rod 84 which in turn supports bags containing fluids to be administered to a patient. A threaded stem 86 engages rod 84 to allow rod 84 to be adjusted in height.

FIG. 7 is a perspective view of heating unit 6, with a cover removed. FIG. 8 is a schematic flow diagram of the unit shown in FIG. 7 and these two Figures will be discussed together.
